# Is A\* Optimal?

	g	h	+
<del>S</del>	<del>0</del>	<del>7</del>	<del>7</del>
S->A	1	6	7
S->G	5	0	5

- What went wrong?
- Actual bad goal cost < estimated good goal cost
- We need estimates to be less than actual costs!

# Admissible Heuristics

---

# Idea: Admissibility

---

Inadmissible (pessimistic) heuristics  
break optimality by trapping  
good plans on the fringe

Admissible (optimistic) heuristics  
slow down bad plans but  
never outweigh true costs

# Admissible Heuristics

- A heuristic  $h$  is *admissible* (optimistic) if:

$$0 \leq h(n) \leq h^*(n)$$

where  $h^*(n)$  is the true cost to a nearest goal

- Examples:

0.0

- Coming up with admissible heuristics is most of what's involved in using  $A^*$  in practice.

# Optimality of A\* Tree Search

---

# Optimality of A\* Tree Search

---

Assume:

- A is an optimal goal node
- B is a suboptimal goal node
- $h$  is admissible

Claim:

- A will exit the fringe before B

# Optimality of A\* Tree Search: Blocking

Proof:

- Imagine B is on the fringe
- Some ancestor  $n$  of A is on the fringe, too (maybe A!)
- Claim:  $n$  will be expanded before B
  1.  $f(n)$  is less or equal to  $f(A)$

$$f(n) = g(n) + h(n)$$

Definition of f-cost

$$f(n) \leq g(A)$$

Admissibility of h

$$g(A) = f(A)$$

$h = 0$  at a goal

# Optimality of A\* Tree Search: Blocking

Proof:

- Imagine B is on the fringe
- Some ancestor  $n$  of A is on the fringe, too (maybe A!)
- Claim:  $n$  will be expanded before B
  - $f(n)$  is less or equal to  $f(A)$
  - $f(A)$  is less than  $f(B)$

$$g(A) < g(B)$$

$$f(A) < f(B)$$

B is suboptimal

$h = 0$  at a goal

# Optimality of A\* Tree Search: Blocking

Proof:

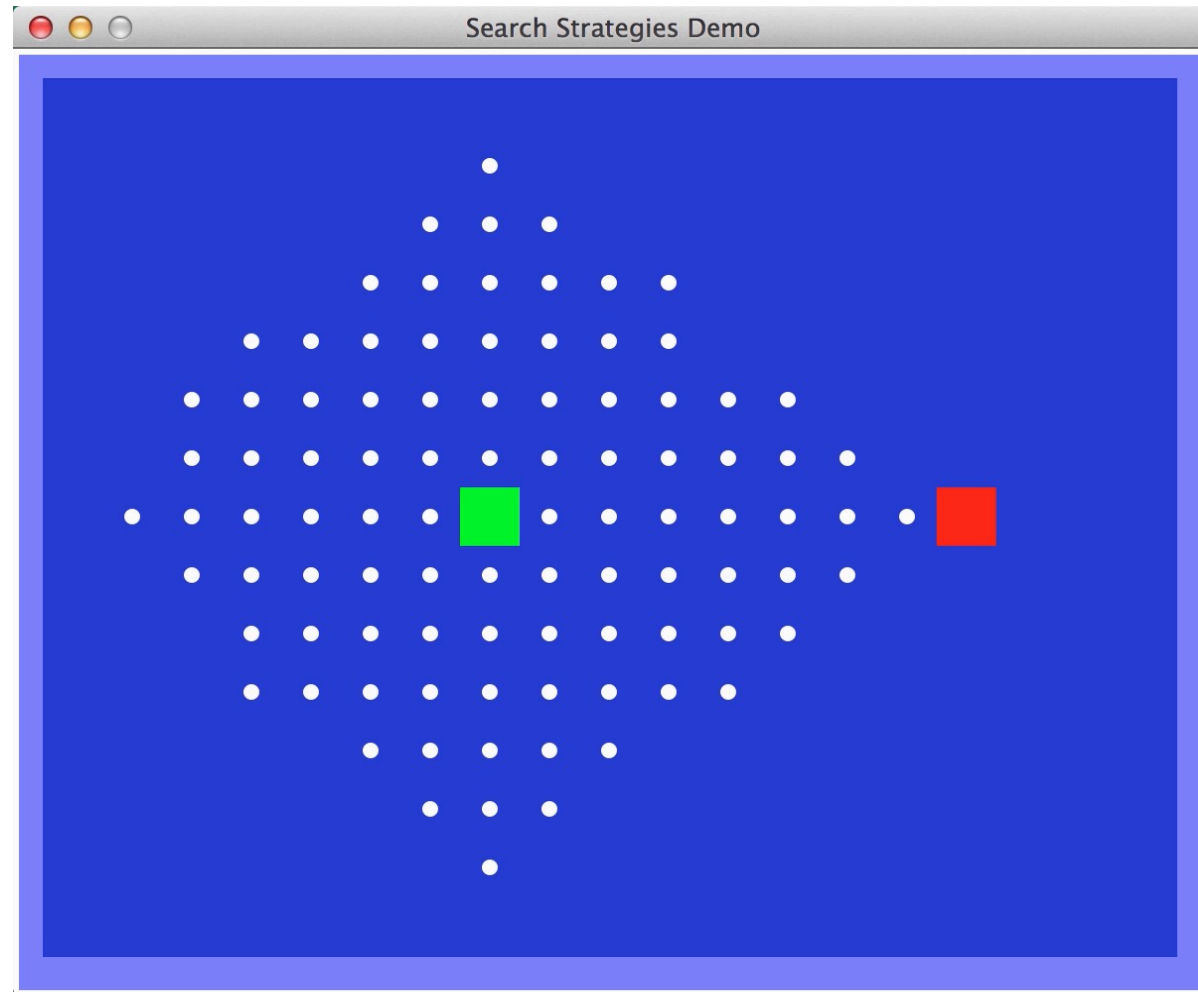

- Imagine B is on the fringe
- Some ancestor  $n$  of A is on the fringe, too (maybe A!)
- Claim:  $n$  will be expanded before B
  1.  $f(n)$  is less or equal to  $f(A)$
  2.  $f(A)$  is less than  $f(B)$
  3.  $n$  expands before B
- All ancestors of A expand before B
- A expands before B
- A\* search is optimal

$$f(n) \leq f(A) < f(B)$$

# Example: 8 Puzzle

7	2	4
5		6
8	3	1

Start State

Actions

	1	2
3	4	5
6	7	8

Goal State

- What are the states?
- How many states?
- What are the actions?
- How many successors from the start state?
- What should the costs be?

Admissible  
heuristics?

# 8 Puzzle I

- Heuristic: Number of tiles misplaced
- Why is it admissible?
- $h(\text{start}) = 8$
- This is a *relaxed-problem* heuristic

Start State

Goal State

	Average nodes expanded when the optimal path has...		
	...4 steps	...8 steps	...12 steps
UCS	112	6,300	$3.6 \times 10^6$
TILES	13	39	227

# 8 Puzzle II

- What if we had an easier 8-puzzle where any tile could slide any direction at any time, ignoring other tiles?
- Total *Manhattan* distance
- Why is it admissible?
- $h(\text{start}) = 3 + 1 + 2 + \dots = 18$

Start State

Goal State

	Average nodes expanded when the optimal path has...		
	...4 steps	...8 steps	...12 steps
TILES	13	39	227
MANHATTAN	12	25	73

# 8 Puzzle III

---

- How about using the *actual cost* as a heuristic?

- Would it be admissible?
- Would we save on nodes expanded?
- What's wrong with it?

- With  $A^*$ : a trade-off between quality of estimate and work per node

- As heuristics get closer to the true cost, you will expand fewer nodes but usually do more work per node to compute the heuristic itself

# Graph Search

---

# Tree Search: Extra Work!

- Failure to detect repeated states can cause exponentially more work.

# Graph Search

- In BFS, for example, we shouldn't bother expanding the circled nodes (why?)

# Graph Search

---

- Idea: never **expand** a state twice
- How to implement:
  - Tree search + set of expanded states (“closed set”)
  - Expand the search tree node-by-node, but...
  - Before expanding a node, check to make sure its state has never been expanded before
  - If not new, skip it, if new add to closed set
- Important: **store the closed set as a set**, not a list
- Can graph search wreck completeness? Why/why not?
- How about optimality?

# A\* Graph Search Gone Wrong?

State space graph

Search tree

Closed Set: S B C A

# Consistency of Heuristics

- Main idea: estimated heuristic costs  $\leq$  actual costs
  - Admissibility: heuristic cost  $\leq$  actual cost to goal
$$h(A) \leq \text{actual cost from A to G}$$
  - Consistency: heuristic “arc” cost  $\leq$  actual cost for each arc
$$h(A) - h(C) \leq \text{cost}(A \text{ to } C)$$
- Consequences of consistency:
  - The f value along a path never decreases
$$h(A) \leq \text{cost}(A \text{ to } C) + h(C)$$
  - A\* graph search is optimal

# Optimality of A\* Search

---

- With a admissible heuristic, Tree A\* is optimal.
- With a consistent heuristic, Graph A\* is optimal.
  - See slides, also video lecture from past years for details.
- With  $h=0$ , the same proofs shows that UCS is optimal.

# Tree Search Pseudo-Code

---

```
function TREE-SEARCH(problem, fringe) return a solution, or failure
  fringe ← INSERT(MAKE-NODE(INITIAL-STATE[problem]), fringe)
  loop do
    if fringe is empty then return failure
    node ← REMOVE-FRONT(fringe)
    if GOAL-TEST(problem, STATE[node]) then return node
    for child-node in EXPAND(STATE[node], problem) do
      fringe ← INSERT(child-node, fringe)
    end
  end
```

# Graph Search Pseudo-Code

---

```
function GRAPH-SEARCH(problem, fringe) return a solution, or failure
  closed ← an empty set
  fringe ← INSERT(MAKE-NODE(INITIAL-STATE[problem]), fringe)
  loop do
    if fringe is empty then return failure
    node ← REMOVE-FRONT(fringe)
    if GOAL-TEST(problem, STATE[node]) then return node
    if STATE[node] is not in closed then
      add STATE[node] to closed
      for child-node in EXPAND(STATE[node], problem) do
        fringe ← INSERT(child-node, fringe)
      end
  end
```

# CS 188: Artificial Intelligence

## Constraint Satisfaction Problems

Instructor: Anca Dragan

University of California, Berkeley

[These slides adapted from Dan Klein and Pieter Abbeel]

# Constraint Satisfaction Problems

---

*N variables*  
*domain D*  
*constraints*

*states*  
*partial assignment*

*goal test*  
*complete; satisfies constraints*

*successor function*  
*assign an unassigned variable*

# What is Search For?

---

- Assumptions about the world: a single agent, deterministic actions, fully observed state, discrete state space
- Planning: sequences of actions
  - The path to the goal is the important thing
  - Paths have various costs, depths
  - Heuristics give problem-specific guidance
- Identification: assignments to variables
  - The goal itself is important, not the path
  - All paths at the same depth (for some formulations)
  - CSPs are specialized for identification problems

# Constraint Satisfaction Problems

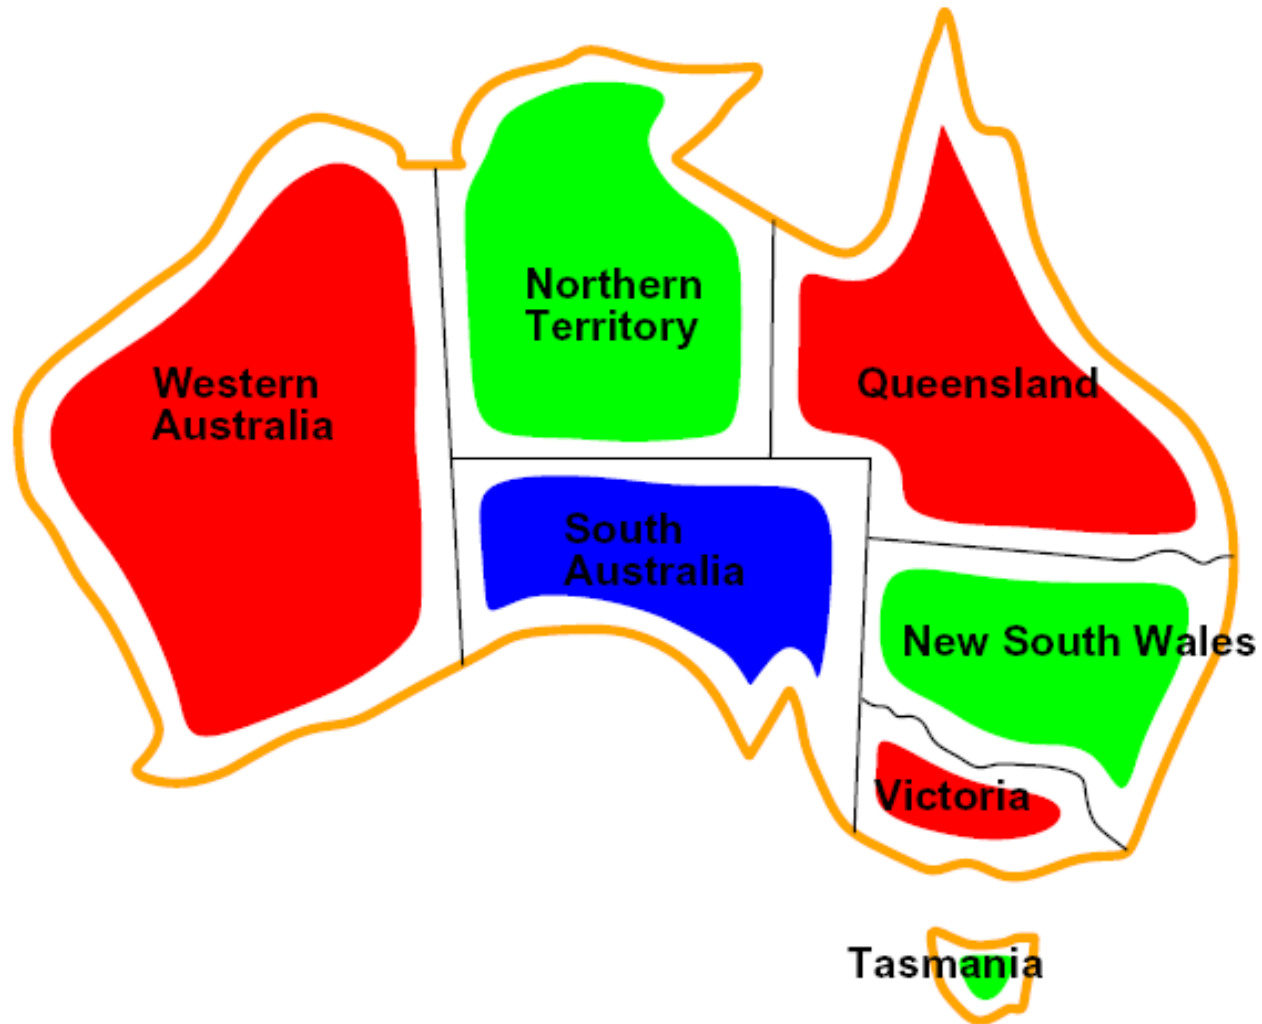

---

- Standard search problems:
  - State is a “black box”: arbitrary data structure
  - Goal test can be any function over states
  - Successor function can also be anything
- Constraint satisfaction problems (CSPs):
  - A special subset of search problems
  - State is defined by **variables  $X_i$**  with values from a **domain  $D$**  (sometimes  $D$  depends on  $i$ )
  - Goal test is a **set of constraints** specifying allowable combinations of values for subsets of variables
- Simple example of a *formal representation language*
- Allows useful general-purpose algorithms with more power than standard search algorithms

# CSP Examples

---

# Example: Map Coloring

- Variables: WA, NT, Q, NSW, V, SA, T
- Domains:  $D = \{\text{red, green, blue}\}$
- Constraints: adjacent regions must have different colors

Implicit:  $WA \neq NT$

Explicit:  $(WA, NT) \in \{(\text{red, green}), (\text{red, blue}), \dots\}$

- Solutions are assignments satisfying all constraints  
 $\{WA=\text{red}, NT=\text{green}, Q=\text{red}, NSW=\text{green}, V=\text{red}, SA=\text{blue}, T=\text{green}\}$

# Example: N-Queens

## ○ Formulation 1:

- Variables:  $X_{ij}$
- Domains:  $\{0, 1\}$
- Constraints

$$\forall i, j, k \quad (X_{ij}, X_{ik}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$\forall i, j, k \quad (X_{ij}, X_{kj}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$\forall i, j, k \quad (X_{ij}, X_{i+k, j+k}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$\forall i, j, k \quad (X_{ij}, X_{i+k, j-k}) \in \{(0, 0), (0, 1), (1, 0)\}$$

$$\sum_{i,j} X_{ij} = N$$

# Example: N-Queens

---

- Formulation 2:

- Variables:  $Q_k$

- Domains:  $\{1, 2, 3, \dots, N\}$

- Constraints:

- Implicit:  $\forall i, j \text{ non-threatening}(Q_i, Q_j)$

- Explicit:  $(Q_1, Q_2) \in \{(1, 3), (1, 4), \dots\}$

- $\dots$

# Example: Cryptarithmic

- Variables:

$F\ T\ U\ W\ R\ O\ X_1\ X_2\ X_3$

- Domains:

$\{0, 1, 2, 3, 4, 5, 6, 7, 8, 9\}$

- Constraints:

$\text{alldiff}(F, T, U, W, R, O)$

$O + O = R + 10 \cdot X_1$

...

$$\begin{array}{r} T\ W\ O \\ +\ T\ W\ O \\ \hline F\ O\ U\ R \end{array}$$

$X_1$

# Example: Sudoku

- Variables:
  - Each (open) square
- Domains:
  - $\{1, 2, \dots, 9\}$
- Constraints:

9-way alldiff for each column

9-way alldiff for each row

9-way alldiff for each region

(or can have a bunch of  
pairwise inequality  
constraints)

# Solving CSPs

---

# Standard Search Formulation

---

- Standard search formulation of CSPs
- States defined by the values assigned so far (partial assignments)
  - Initial state: the empty assignment,  $\{\}$
  - Successor function: assign a value to an unassigned variable
  - Goal test: the current assignment is complete and satisfies all constraints
- We'll start with the straightforward, naïve approach, then improve it

# Search Methods

- What would BFS do?

{ }

{WA=g} {WA=r} ... {NT=g} ...

# Search Methods

---

- What would BFS do?

- What would DFS do?

  - let's see!

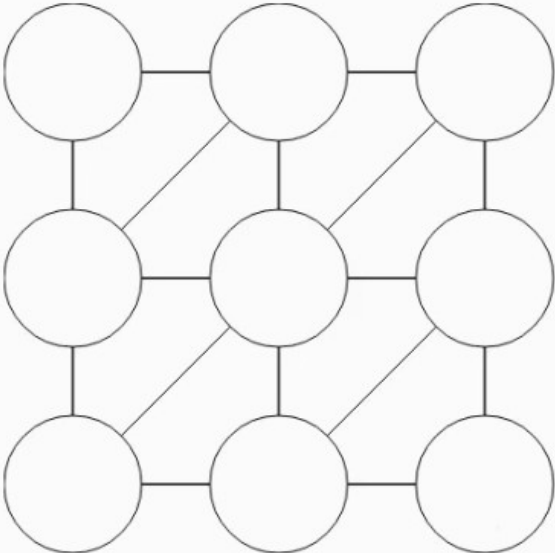

- What problems does naïve search have?

# Video of Demo Coloring -- DFS

# Backtracking Search

---

# Backtracking Search

---

- Backtracking search is the basic uninformed algorithm for solving CSPs
- Idea 1: One variable at a time
  - Variable assignments are commutative, so fix ordering -> better branching factor!
  - I.e., [WA = red then NT = green] same as [NT = green then WA = red]
  - Only need to consider assignments to a single variable at each step
- Idea 2: Check constraints as you go
  - I.e. consider only values which do not conflict previous assignments
  - Might have to do some computation to check the constraints
  - “Incremental goal test”
- Depth-first search with these two improvements is called *backtracking search* (not the best name)
- Can solve n-queens for  $n \approx 25$

# Backtracking Example

[Demo: coloring -- backtracking]

# Video of Demo Coloring – Backtracking

The screenshot displays a web browser window at the URL `beta.cs188.org/exercises/csps/forward_checking/forward_checking.html`. The main content area features a 3x3 grid of nine circular nodes connected by lines, representing a graph. To the right of the graph, there are several configuration sections:

- Graph**: A dropdown menu set to "Simple".
- Algorithm**: A dropdown menu set to "Backtracking".
- Ordering**: Three radio buttons: "None" (selected), "MRV", and "MRV with LCV".
- Filtering**: Three radio buttons: "None" (selected), "Forward Checking", and "Arc Consistency".
- Speed**: Two input fields: "Speedup" set to "1" with a multiplier "x", and "Frame Delay" set to "700".

Below the graph, there is a row of control buttons: "Reset", "Prev", "Pause", "Next", "Play", and "Faster". A mouse cursor is hovering over the "Next" button. The bottom of the image shows a Windows taskbar with various application icons and a system tray on the right indicating 100% battery, signal strength, and the date/time: 11:46 AM, 9/4/2012.

# Backtracking Search

```
function BACKTRACKING-SEARCH(csp) returns solution/failure
  return RECURSIVE-BACKTRACKING({ }, csp)

function RECURSIVE-BACKTRACKING(assignment, csp) returns soln/failure
  if assignment is complete then return assignment
  var ← SELECT-UNASSIGNED-VARIABLE(VARIABLES[csp], assignment, csp)
  for each value in ORDER-DOMAIN-VALUES(var, assignment, csp) do
    if value is consistent with assignment given CONSTRAINTS[csp] then
      add {var = value} to assignment
      result ← RECURSIVE-BACKTRACKING(assignment, csp)
      if result ≠ failure then return result
      remove {var = value} from assignment
  return failure
```

- Backtracking = DFS + variable-ordering + fail-on-violation
- What are the choice points?
