### CS 188: Artificial Intelligence

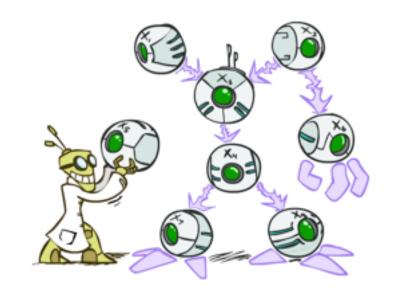

Bayes' Nets: Inference

Instructors: Jacob Andreas and Davis Foote --- University of California, Berkeley

### Bayes' Net Representation

- A directed, acyclic graph, one node per random variable
- A conditional probability table (CPT) for each node
  - A collection of distributions over X, one for each combination of parents' values  $P(X|a_1\dots a_n)$

- Bayes' nets implicitly encode joint distributions
  - As a product of local conditional distributions
  - To see what probability a BN gives to a full assignment, multiply all the relevant conditionals together:

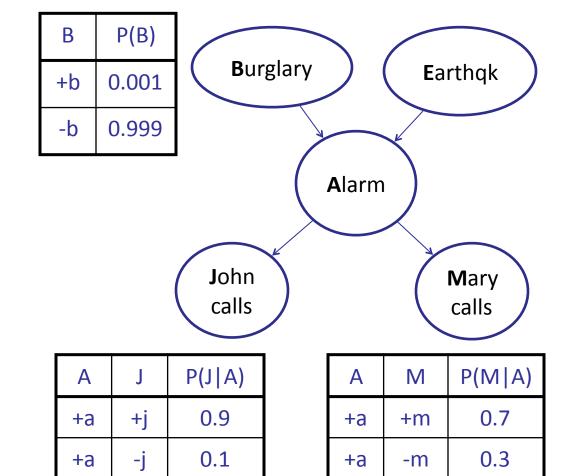

$$P(x_1, x_2, \dots x_n) = \prod_{i=1}^n P(x_i | parents(X_i))$$

# Example: Treasure Hunting Pacman

### Example: Treasure Hunting Pacman

# Bayes' Nets

- ✓ Representation
- ✓ Conditional Independences
- Probabilistic Inference
  - Enumeration (exact, exponential complexity)
  - Variable elimination (exact, worst-case exponential complexity, often better)
  - Inference is NP-complete
  - Sampling (approximate)
- Learning Bayes' Nets from Data

#### Inference

 Inference: calculating some useful quantity from a joint probability distribution

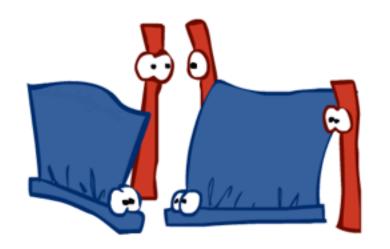

#### Examples:

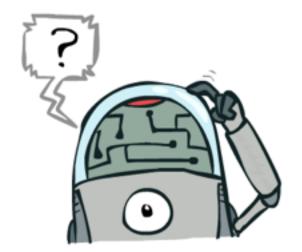

Posterior probability

$$P(Q|E_1 = e_1, \dots E_k = e_k)$$

Most likely explanation:

$$\operatorname{argmax}_q P(Q = q | E_1 = e_1 \dots)$$

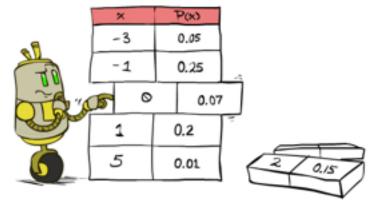

### Inference by Enumeration

#### General case:

 $E_1 \dots E_k = e_1 \dots e_k$  Q  $X_1, X_2, \dots X_n$   $All \ variables$ Evidence variables: Query\* variable: Hidden variables:

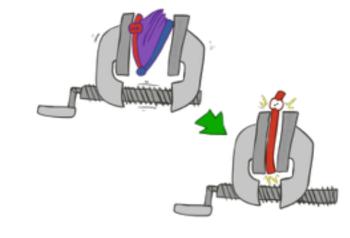

> Step 2: Sum out H to get joint of Query and evidence

Step 1: Select the

the evidence

entries consistent with

$$P(Q, e_1 \dots e_k) = \sum_{h_1 \dots h_r} P(Q, h_1 \dots h_r, e_1 \dots e_k)$$
$$X_1, X_2, \dots X_n$$

We want:

$$P(Q|e_1 \dots e_k)$$

\* Works fine with multiple query variables, too

Step 3: Normalize

$$\times \frac{1}{Z}$$

$$Z = \sum_{q} P(Q, e_1 \cdots e_k)$$
$$P(Q|e_1 \cdots e_k) = \frac{1}{Z} P(Q, e_1 \cdots e_k)$$

### Inference by Enumeration in Bayes' Net

- Given unlimited time, inference in BNs is easy
- Reminder of inference by enumeration by example:

$$P(B \mid +j,+m) \propto_B P(B,+j,+m)$$

$$= \sum_{e,a} P(B, e, a, +j, +m)$$

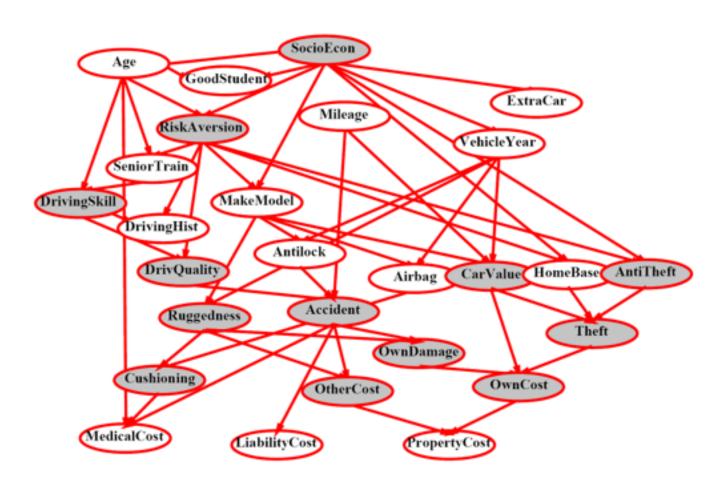

$$= \sum P(B)P(e)P(a|B,e)P(+j|a)P(+m|a)$$

$$= \sum_{e,a} P(B)P(e)P(a|B,e)P(+j|a)P(+m|a)$$

$$= P(B)P(+e)P(+a|B,+e)P(+j|+a)P(+m|+a) + P(B)P(+e)P(-a|B,+e)P(+j|-a)P(+m|-a)$$

$$= P(B)P(-e)P(+a|B,-e)P(+j|+a)P(+m|+a) + P(B)P(-e)P(-a|B,-e)P(+j|-a)P(+m|-a)$$

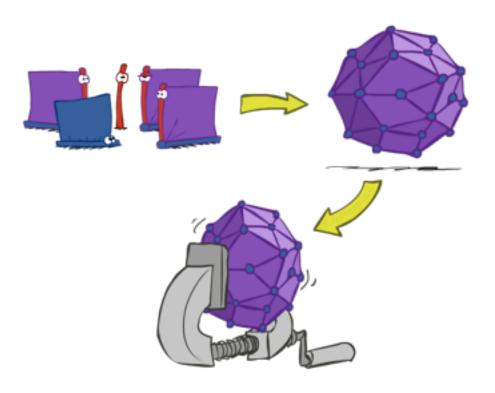

# Inference by Enumeration?

 $P(Antilock|observed\ variables) = ?$ 

### Inference by Enumeration vs. Variable Elimination

- Why is inference by enumeration so slow?
  - You join up the whole joint distribution before you sum out the hidden variables

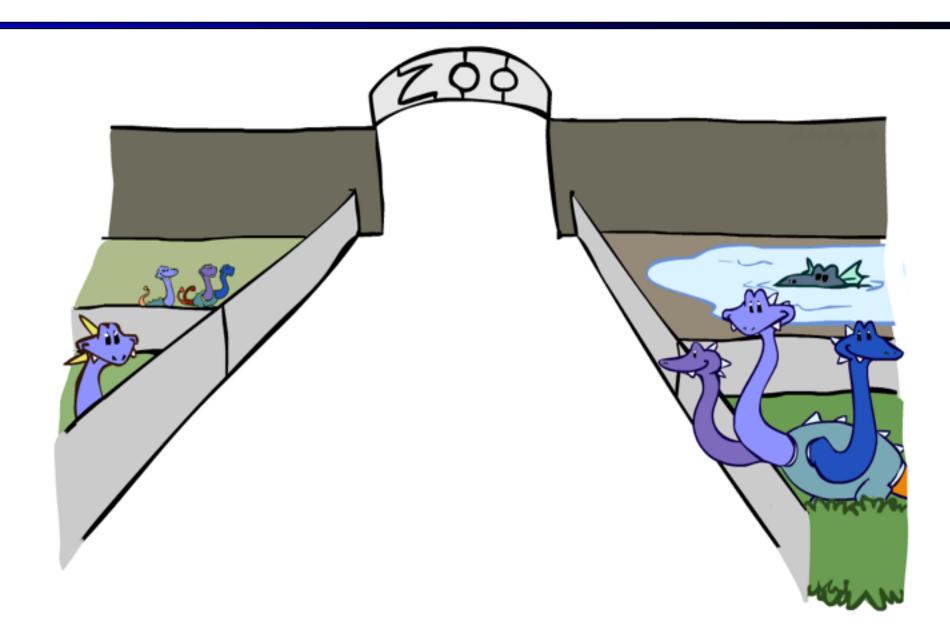

- Idea: interleave joining and marginalizing!
  - Called "Variable Elimination"
  - Still NP-hard, but usually much faster than inference by enumeration

First we'll need some new notation: factors

### Factor Zoo

#### Factor Zoo I

- Joint distribution: P(X,Y)
  - Entries P(x,y) for all x, y
  - Sums to 1

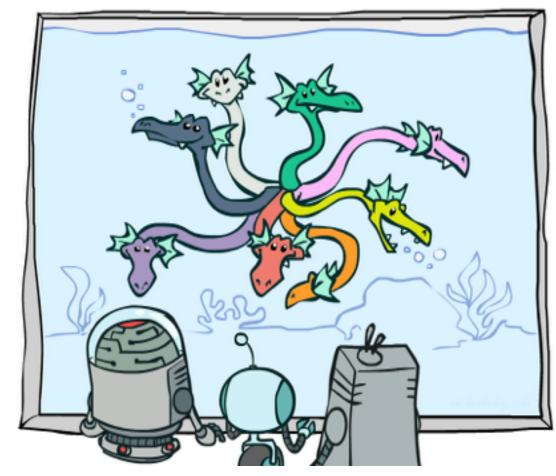

- Selected joint: P(x,Y)
  - A slice of the joint distribution
  - Entries P(x,y) for fixed x, all y
  - Sums to P(x)
- Number of capitals = dimensionality of the table

#### P(T,W)

Т	W	Р
hot	sun	0.4
hot	rain	0.1
cold	sun	0.2
cold	rain	0.3

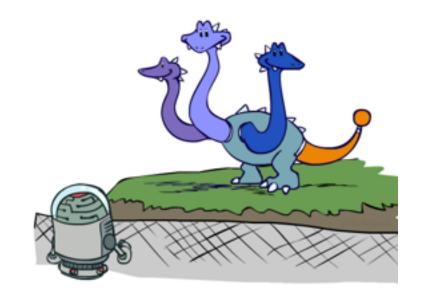

#### P(cold, W)

Η	W	Р
cold	sun	0.2
cold	rain	0.3

#### Factor Zoo II

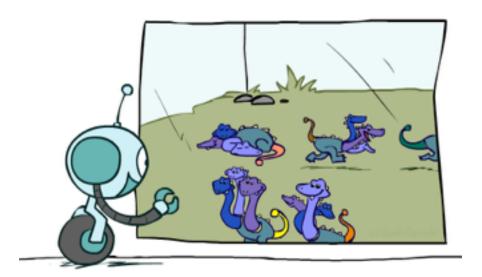

- Single conditional: P(Y | x)
  - Entries P(y | x) for fixed x, all y
  - Sums to 1

#### P(W|cold)

Т	W	Р
cold	sun	0.4
cold	rain	0.6

- Family of conditionals:
  - P(X | Y)
    - Multiple conditionals
    - Entries P(x | y) for all x, y
    - Sums to |Y|

#### P(W|T)

Т	W	Р	
hot	sun	0.8	
hot	rain	0.2	
cold	sun	0.4	
cold	rain	0.6	  -

P(W|hot)

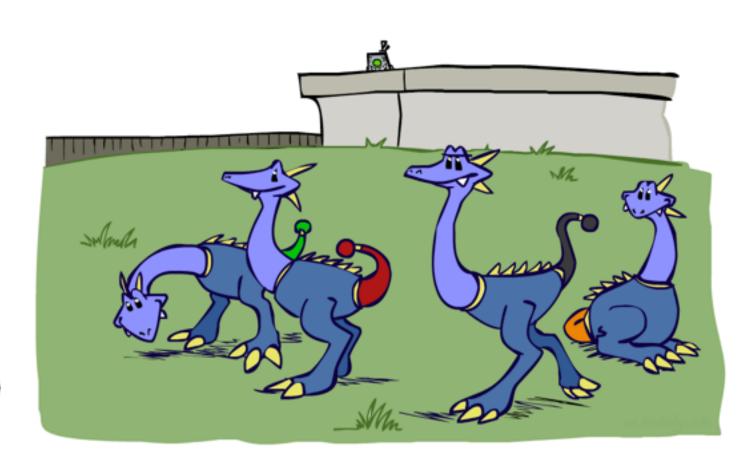

P(W|cold)

#### Factor Zoo III

- Specified family: P( y | X )
  - Entries P(y | x) for fixed y,but for all x
  - Sums to ... who knows!

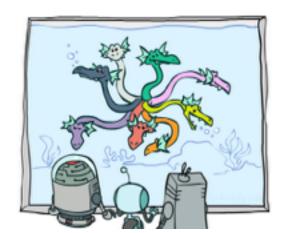

#### P(rain|T)

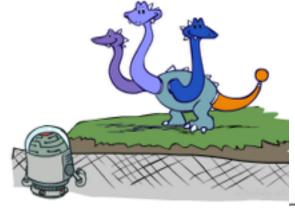

Т	W	Р	
hot	rain	0.2	P(rain hot)
cold	rain	0.6	P(rain cold)

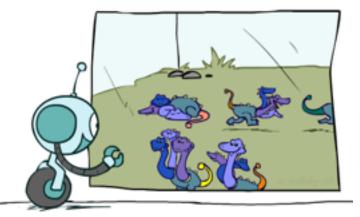

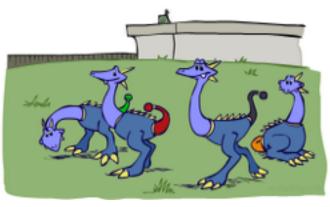

### Factor Zoo Summary

- In general, when we write  $P(Y_1 ... Y_N \mid X_1 ... X_M)$ 
  - It is a "factor," a multi-dimensional array
  - Its values are  $P(y_1 ... y_N \mid x_1 ... x_M)$
  - Any assigned (=lower-case) X or Y is a dimension missing (selected) from the array

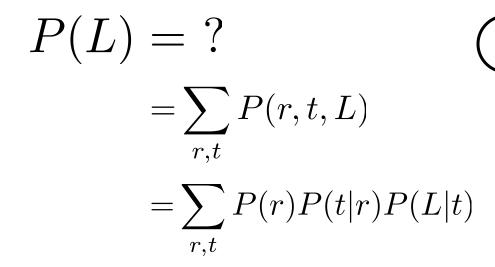

### Example: Traffic Domain

+t	-	0.7
-t	+	0.1
-t	-	0.9

- Any known values are selected
  - ullet E.g. if we know  $L=+\ell$  the initial factors are

+r	0.1
-r	0.9

$$P(T|R)$$
  $P(+\ell|T)$ 

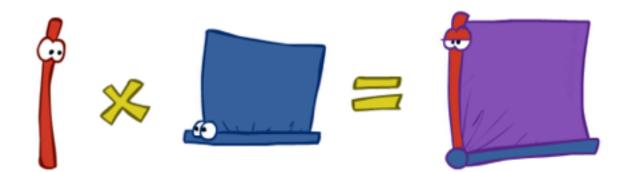

+t	+	0.3
-t	+	0.1

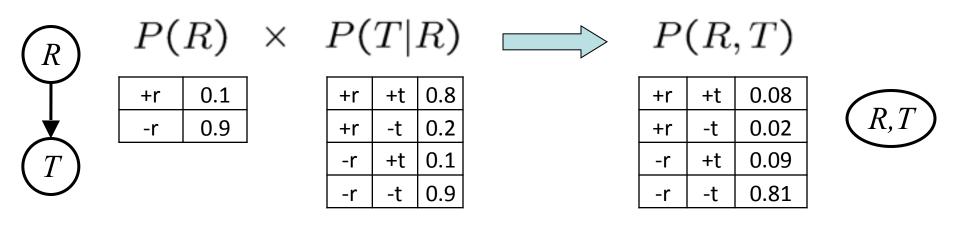

Procedure: Join all factors, then eliminate all hidden variables

#### **Operation 1: Join Factors**

- First basic operation: joining factors
- Combining factors:
  - Just like a database join
  - Get all factors over the joining variable
  - Build a new factor over the union of the variables involved

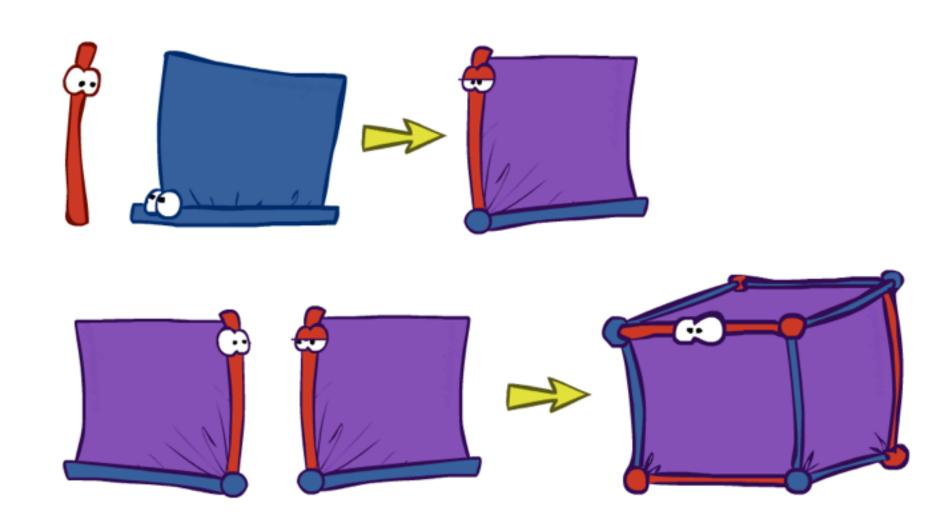

- Example: Join on R
  - Computation for each entry: pointwise products

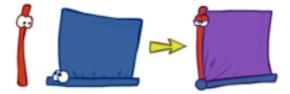

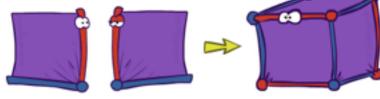

$$\forall r, t : P(r,t) = P(r) \cdot P(t|r)$$

# Example: Multiple Joins

### Example: Multiple Joins

+r	0.1

-r	+t	-1	0.063
-r	-t	+	0.081
-r	-t	-1	0.729

R

### Operation 2: Eliminate

Second basic operation: marginalization

Take a factor and sum out a variable

- Shrinks a factor to a smaller one
- A projection operation

#### Example:

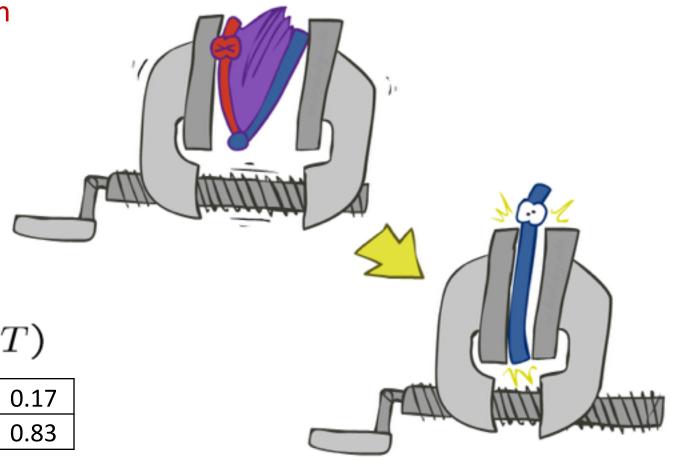

P(R,T)

+r	+t	0.08
+r	-t	0.02
-r	+t	0.09
-r	-t	0.81

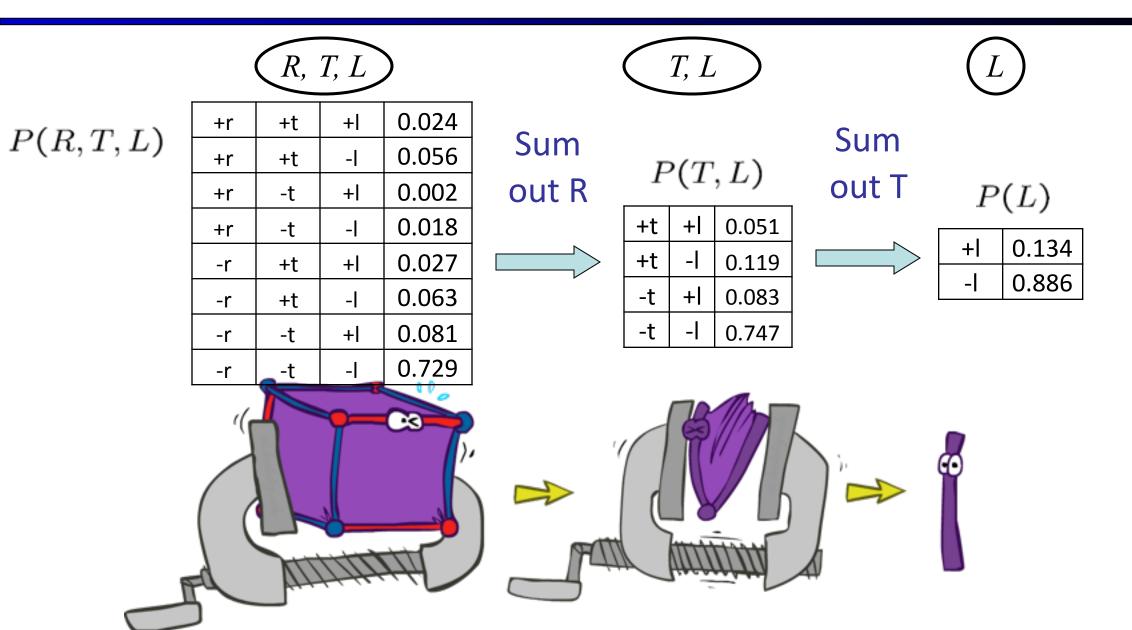

sum R

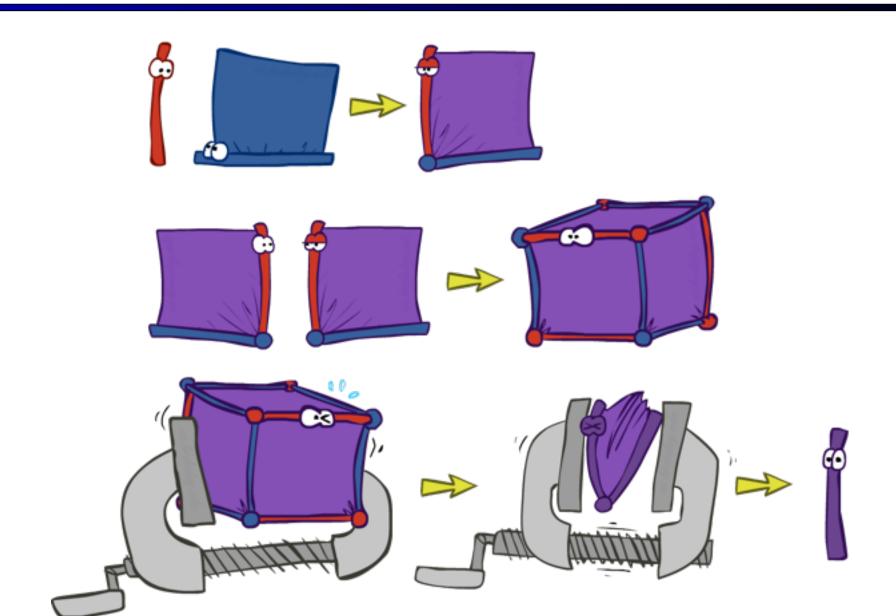

+t	0.17
-t	0.83

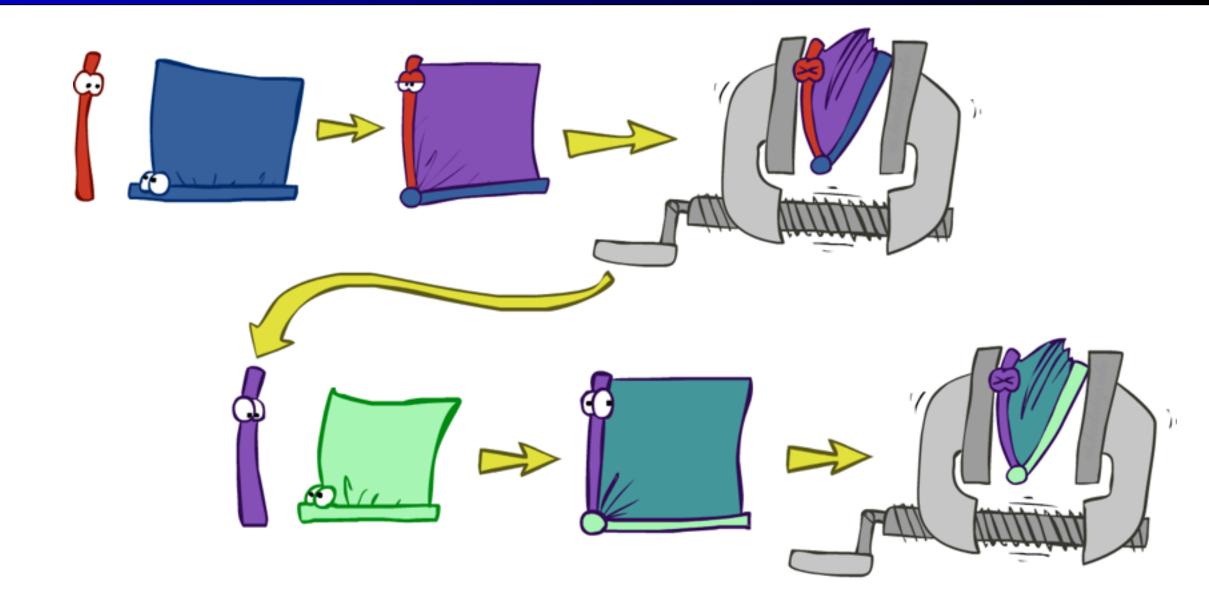

### Multiple Elimination

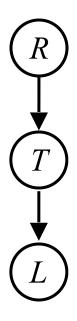

Thus Far: Multiple Join, Multiple Eliminate (= Inference by Enumeration)

# Marginalizing Early (= Variable Elimination)

#### **Traffic Domain**

$$P(L) = ?$$

Inference by Enumeration

$$= \sum_t \sum_r P(L|t)P(r)P(t|r)$$
 Join on  $t$  Eliminate  $t$ 

Variable Elimination

$$= \sum_{t} P(L|t) \sum_{r} P(r) P(t|r)$$
 Join on r Eliminate r

# Marginalizing Early! (aka VE)

0.1

0.9

#### Join R P(R,T)

8(
)2
)9
_

0.81

#### Sum out R

#### P(T)

+t	0.17
-t	0.83

#### Join T

#### Sum out T

#### P(T|R)

+r

+r	+t	0.8
+r	-t	0.2
-r	+t	0.1
-r	-t	0.9

-r	-t	0.9

P(L)	T
~ (~	l

	_	
+t	+	0.3
+t	-1	0.7
-t	+	0.1
-t	-	0.9

R, T

#### P(L|T)

+t	+	0.3
+t	<del>-</del> -	0.7
-t	+	0.1
-t	-	0.9

# T

#### P(L|T)

	_	
+t	+	0.3
+t	-1	0.7
-t	+	0.1
-t	-1	0.9

#### P(T,L)

+t	+	0.051
+t	<del>-</del> -	0.119
-t	+	0.083
-t	-	0.747

P(L)

+	0.134
-	0.866

#### Evidence

- If evidence, start with factors that select that evidence
  - No evidence uses these initial factors:

D	1	D	١
Γ	ĺ	$\boldsymbol{n}$	J

+r	0.1
-r	0.9

+r	+t	0.8
+r	-t	0.2
-r	+t	0.1
-r	-t	0.9

$$P(T|R)$$
  $P(L|T)$ 

+t	+	0.3
+t	7	0.7
-t	+	0.1
-t	-	0.9

ullet Computing P(L|+r) , the initial factors become:

$$P(+r)$$

$$P(+r)$$
  $P(T|+r)$   $P(L|T)$ 

+r	+t	0.8
+r	-t	0.2

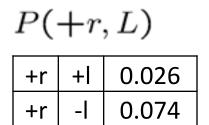

+t	+	0.3
+t	7	0.7
-t	+	0.1
-t	-1	0.9

We eliminate all vars other than query + evidence

#### Evidence II

- Result will be a selected joint of query and evidence
  - E.g. for P(L | +r), we would end up with:

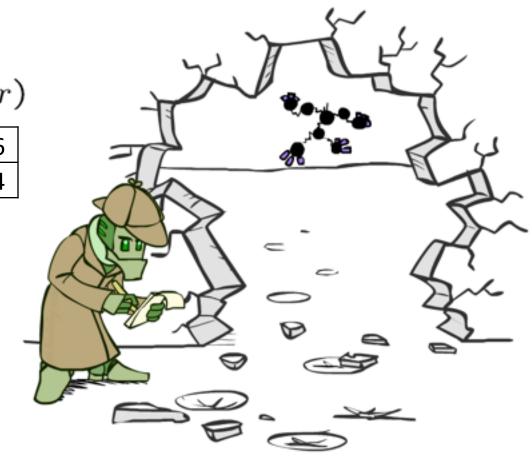

P(L	+	r)
•		

+	0.26
-	0.74

To get our answer, just normalize this!

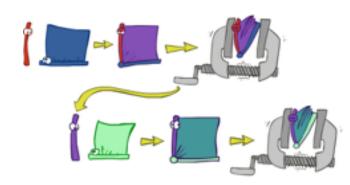

#### General Variable Elimination

- Query:  $P(Q|E_1 = e_1, \dots E_k = e_k)$
- Start with initial factors:
  - Local CPTs (but instantiated by evidence)
- While there are still hidden variables (not Q or evidence):
  - Pick a hidden variable H
  - Join all factors mentioning H
  - Eliminate (sum out) H
- Join all remaining factors and normalize

$$i \cdot \mathbf{r} = \mathbf{r} \times \frac{1}{Z}$$

### Example

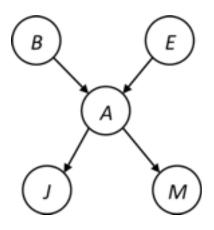

P(E)

P(A|B,E)

P(j|A)

P(m|A)

#### Choose A

P(m|A)

P(j, m, A|B, E)  $\sum$  P(j, m|B, E)

P(E)

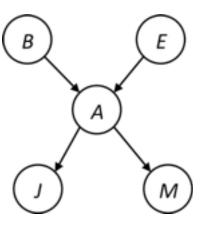

P(j,m|B,E)

### Example

P(B)

P(E)

P(j,m|B,E)

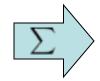

Choose E

P(j,m|B,E)

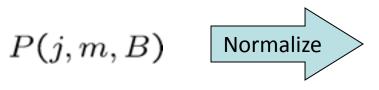

P(j, m, E|B)

P(j,m|B)

Finish with B

P(B|j,m)

### Same Example in Equations

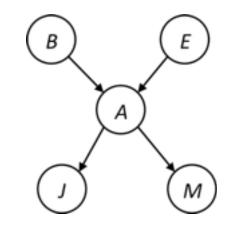

$$P(B|j,m) \propto P(B,j,m)$$

P(B) P(E)

P(E) P(A|B,E)

P(j|A)

P(m|A)

$$P(B|j,m) \propto P(B,j,m)$$

$$=\sum_{e,a}P(B,j,m,e,a)$$

$$= \sum_{e,a} P(B)P(e)P(a|B,e)P(j|a)P(m|a)$$

$$= \sum_{e} P(B)P(e) \sum_{a} P(a|B,e)P(j|a)P(m|a)$$

$$= \sum_{e} P(B)P(e)f_1(B, e, j, m)$$

$$= P(B) \sum_{e} P(e) f_1(B, e, j, m)$$

$$= P(B)f_2(B,j,m)$$

marginal can be obtained from joint by summing out

use Bayes' net joint distribution expression

use 
$$x^*(y+z) = xy + xz$$

joining on a, and then summing out gives f<sub>1</sub>

use 
$$x*(y+z) = xy + xz$$

joining on e, and then summing out gives f<sub>2</sub>

#### Another Variable Elimination Example

Query: 
$$P(X_3|Y_1 = y_1, Y_2 = y_2, Y_3 = y_3)$$

Start by inserting evidence, which gives the following initial factors:

$$p(Z)p(X_1|Z)p(X_2|Z)p(X_3|Z)p(y_1|X_1)p(y_2|X_2)p(y_3|X_3)$$

Eliminate  $X_1$ , this introduces the factor  $f_1(Z, y_1) = \sum_{x_1} p(x_1|Z)p(y_1|x_1)$ , and we are left with:

$$p(Z)f_1(Z, y_1)p(X_2|Z)p(X_3|Z)p(y_2|X_2)p(y_3|X_3)$$

Eliminate  $X_2$ , this introduces the factor  $f_2(Z, y_2) = \sum_{x_2} p(x_2|Z)p(y_2|x_2)$ , and we are left with:

$$p(Z)f_1(Z, y_1)f_2(Z, y_2)p(X_3|Z)p(y_3|X_3)$$

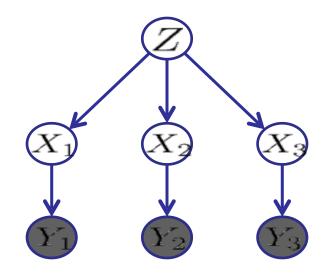

Eliminate Z, this introduces the factor  $f_3(y_1, y_2, X_3) = \sum_z p(z) f_1(z, y_1) f_2(z, y_2) p(X_3|z)$ , and we are left:

$$p(y_3|X_3), f_3(y_1, y_2, X_3)$$

No hidden variables left. Join the remaining factors to get:

$$f_4(y_1, y_2, y_3, X_3) = P(y_3|X_3)f_3(y_1, y_2, X_3).$$

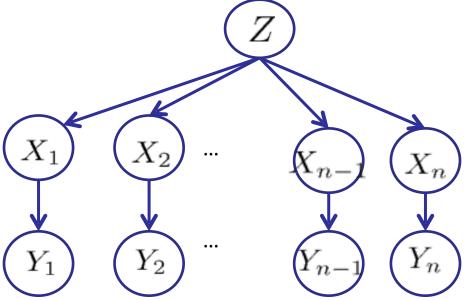

Normalizing over  $X_3$  gives  $P(X_3|y_1, y_2, y_3)$ .

Computational complexity critically depends on the largest factor being generated in this process. Size of factor = number of entries in table. In example above (assuming binary) all factors generated are of size 2 --- as they all only have one variable (Z, Z, and X<sub>3</sub> respectively).

### Variable Elimination Ordering

For the query  $P(X_n | y_1,...,y_n)$  work through the following two different orderings as done in previous slide:  $Z, X_1, ..., X_{n-1}$  and  $X_1, ..., X_{n-1}$ , Z. What is the size of the maximum factor generated for each of the orderings?

- Answer: 2<sup>n+1</sup> versus 2<sup>2</sup> (assuming binary)
- In general: the ordering can greatly affect efficiency.

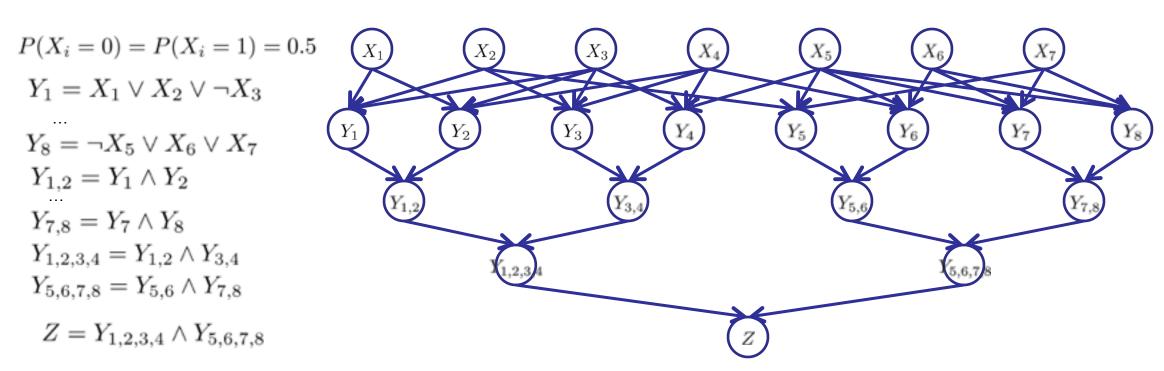

#### VE: Computational and Space Complexity

- The computational and space complexity of variable elimination is determined by the largest factor
- The elimination ordering can greatly affect the size of the largest factor.
  - E.g., previous slide's example 2<sup>n</sup> vs. 2
- Does there always exist an ordering that only results in small factors?
  - No!

### Worst Case Complexity?

#### CSP:

$$(x_1 \lor x_2 \lor \neg x_3) \land (\neg x_1 \lor x_3 \lor \neg x_4) \land (x_2 \lor \neg x_2 \lor x_4) \land (\neg x_3 \lor \neg x_4 \lor \neg x_5) \land (x_2 \lor x_5 \lor x_7) \land (x_4 \lor x_5 \lor x_6) \land (\neg x_5 \lor x_6 \lor \neg x_7) \land (\neg x_5 \lor \neg x_6 \lor x_7) \land (x_4 \lor x_5 \lor x_6) \lor (x_4 \lor x_6)$$

- If we can answer P(z) equal to zero or not, we answered whether the 3-SAT problem has a solution.
- Hence inference in Bayes' nets is NP-hard. No known efficient probabilistic inference in general.

### Polytrees

- A polytree is a directed graph with no undirected cycles
- For poly-trees you can always find an ordering that is efficient
  - Try it!!
- Cut-set conditioning for Bayes' net inference
  - Choose set of variables such that if removed only a polytree remains
  - Exercise: Think about how the specifics would work out!

# Bayes' Nets
